Statement of Use

Information in this document is to help biologists in the Agency to identify where analytical errors occur so that they can be reduced or eliminated. Data in the tables provide measures of the accuracy of primary data produced in accordance with the standard methods for the River Invertebrate Prediction and Classification System (RIVPACS) and analysed to the level required for the Biological Monitoring Working Party (BMWP)-score system, including General Quality Assessment. Information in this report may be used to determine statistical confidence limits and the statistical significances of differences between biological samples. This includes comparisons of Observed/Expected (O/E) values and quality bands made by the compare module of RIVPACS III+ and the statistical routine CONCLASS used for GQA surveys.

1. INTRODUCTION

The collection of standard macro-invertebrate samples and their analysis to the level required for the Biological Monitoring Working Party (BMWP) system is the most widely used biological technique for evaluating river quality in the water industry in the United Kingdom. Used with the computer model RIVPACS (River Invertebrate Prediction and Classification System) developed by the Centre for Ecology and Hydrology (CEH), they are the basis for the Agency's biological classification of water quality. This is used for national General Quality Assessment (GQA) river quality surveys and one of the government's Headline Indicators of environmental quality, as well as for purely operational purposes including Catchment Abstraction Management Strategies, drought orders and drought permits, and determining appropriate discharge consents. These samples are also used for assessing pollution and setting priorities for capital investment. Data from these samples are made available to the public. An independent audit of these biological samples is required to ensure that a high and consistent standard of sorting and identification is maintained; to assess the proficiency of the internal laboratory analytical quality control (AQC) inspection and to demonstrate the quality of the data to its users.

In 2001, biological monitoring of rivers was undertaken by the Environment Agency (The Agency) in England and Wales, the Scottish Environment Protection Agency (SEPA) in Scotland, the Industrial Research and Technology Unit (IRTU) in Northern Ireland and the Government Laboratory in the Isle of Man. Each organisation employed standard collection procedures (Murray-Bligh, 1999a) to ensure that the data collected were compatible with RIVPACS. Each Environment Agency laboratory appointed at least one experienced analyst to act as an internal analytical quality control (AQC) inspector. These inspectors re-sorted a random selection of 1 in every 10 of their laboratory's standard samples. In addition, CEH was contracted to undertake an independent external audit of the quality of the laboratories' analyses of standard biological samples. This commission was consistent with the audit performed by CEH staff for the national River Quality Surveys in 1990, 1995 and 2000 and for the biological monitoring and assessment surveys each year between 1991 and 1994 and between 1996 and 1999. The audit for the Agency comprised two elements. The AQC Audit provided a measure of the quality of the AQC inspection and was used to adjust the control parameters of the AQC scheme for each laboratory. The Primary Audit provided an independent measure of the quality of the data from each laboratory (data was not adjusted for errors identified by the audit) and hence the errors in biotic indices calculated from that data. The net error in number of BMWP-scoring taxa (bias) was used to determine confidence limits of EQIs and the probabilities of sites belonging to each grade of the Agency's GQA environmental quality classification, and the probabilities of changes or differences in grade (see Section 5).

For 2001, CEH were contracted to audit 520 samples for the Agency. However, an outbreak of Foot and Mouth Disease led to a restriction on the movement of Agency staff, severely curtailing their sampling programme in spring 2001, so some laboratories did not send their full quota of samples for audit. This report presents the results of the audit of 423 samples that were sorted and identified by the Agency's primary analysts. The results of the AQC Audit, detailing the quality of the Agency's internal AQC inspections of these samples, are reported separately (Gunn *et al.*, 2002).

2. SAMPLE SELECTION

Samples for audit were selected internally by each of the organisations being audited. The precise manner of sample selection, which biologists would be monitored and the number of audit samples from each season, were left to the discretion of the organisation, within the limits of the total number of samples that CEH was contracted to audit. The standard method of selection used by the Agency is

described in Murray-Bligh (1999b). Each Agency laboratory should have randomly selected for audit 20 samples that had been analysed twice (once for primary analysis and once for internal AQC inspection). However, if there were insufficient AQC-inspected samples to make up the laboratory's quota by the deadline for dispatch to CEH, primary samples that had been analysed just once were sent instead. The biologists analysing these samples had no prior knowledge of which samples were to be audited.

3. SAMPLE PROCESSING

The normal protocol for Agency biologists was to sort their samples, either live or preserved, in the laboratory. Samples were sorted for all families of aquatic macro-invertebrates and examples of each taxon were removed. The specimens were placed in a vial of preservative (70% industrial alcohol) and the taxa present were recorded on a standard data sheet. The vial of animals and the bulk of the sample were then returned to the sample container and preservative added. Samples were re-sorted for internal AQC inspection in the same manner as the primary analysis. The AQC inspector's task included confirming the identification of the contents of the vial and ensuring that the results recorded on the data sheet were correct. Any additional taxa found in the AQC inspection were to be put in a separate vial so that the contents of the primary analyst's vial was not altered, although this instruction was not always followed.

Each sample available to CEH for audit should have included:

- i) A vial or vials containing representatives from each family.
- ii) A data sheet containing a list of the families to be found in the vial(s).
- iii) The preserved sample.

When these three elements were present, the sequence of operations at CEH was as follows:

- a) The remainder of the sample was sorted, without reference to the data sheet or to the vial of animals, and the families of aquatic macro-invertebrates were identified.
- b) The families contained within the vial(s) were identified.
- c) The list of families recorded on the data sheet was compared with those found in the sample by the CEH auditor.
- d) The list of families recorded on the data sheet was compared with those identified from the vial(s) by the CEH auditor.
- e) "Losses", "gains" and "omissions" from the list of families recorded on the data sheet were noted. In the case of "gains", each additional family was identified to species, where possible, so that species causing repeated errors could be noticed. Any "gains" represented in the sample by a single specimen were noted as such.
- f) For each "loss" or "gain", the CEH auditor selected a code from a list at the foot of the result sheet to indicate the most likely cause of the error.

Definitions

Losses are taxa recorded as present by the analyst whose quality was being audited, but that were not found in the vial or sample by the auditor. Gains are taxa found in the vial or sample by the auditor, that were not recorded as present by the analyst whose quality was being audited. Omissions are taxa that were recorded as present by the analyst whose quality is being audited, and that the auditors found in the sample, but not in the vial.

Occasionally a sample did not include a vial containing representative examples of the families recorded on the data sheet, while some arrived with the vial damaged in transit such that the

representative specimens were no longer separated. For these samples, only operations a), c), e) and f) above were appropriate.

Several directives were issued to CEH relating to the treatment of macro-invertebrate taxa. Every taxon recorded on the data sheet must have been supported by a voucher specimen of that family in the vial (or, for very large specimens, left in the sample). The only exceptions to this rule were the native crayfish, *Austropotamobius pallipes*, the medicinal leech, *Hirudo medicinalis* and the pearl mussel, *Margaritifera margaritifera*, all of which are protected species. Animals deemed to have been dead at the time of sampling, cast insect skins, pupal exuviae and empty mollusc shells were to be excluded from the list of families recorded on the data sheet as present. Isolated posterior ends of "living" specimens were not acceptable as records of a taxon. In these cases, thorax plus abdomen was deemed acceptable but abdomen only was deemed unacceptable. Terrestrial representatives of families were also to be excluded from the audit. Clambidae, Chrysomelidae and Curculionidae, which appear in the original BMWP list, were excluded because most representatives of these families are terrestrial and they are excluded from the BMWP-score system as currently used in the UK, including the Agency's GQA classification. Trichopteran pupae were to be included in the listing of families as they were to be identified by Agency biologists.

4. REPORTING

The results of each sample audit were recorded on a standard report form (see Figs 1 & 2) and sent to the Agency's Project Manager and to the Area and Regional Biologists. For audit samples where a vial of animals was included, the comparison between the families recorded on the data sheet and the taxa found in the vial by CEH was shown in the section of the report form headed "VIAL". Discrepancies could be caused by misidentifications or by mistakes in recording the results on the data sheet. Families not recorded on the data sheet but found by CEH in the remainder of the sample were entered in the section of the report form headed "SAMPLE" under "Additional taxa found in sample". For Primary Audit results, this section also included taxa added by the internal AQC inspector. Taxa recorded here represent families missed by the analyst(s) on sorting the sample. When the families listed as "losses" in the first section of the report form were compared with the full list of families recorded in the sample by CEH, some apparent losses from the vial were offset by the presence of those families in the remainder of the sample. These taxa were therefore listed both as "losses" from the vial and as "gains" from the sample and were neither a net loss nor a net gain. These families were marked with an asterisk in both sections to highlight this fact. These errors were recorded as "omissions". They were usually caused by an analyst forgetting to place an example of the taxon in the vial, although occasionally they occurred when an animal in the vial had been misidentified, but the CEH auditor subsequently found the recorded taxon in the sample.

Species identifications, state of development (e.g. adult or larval coleopterans) and the presence of a single representative of a family were recorded in the centre section of the audit report form.

CEH was asked to interpret each error to suggest its probable cause. An error code, selected from a list of options at the foot of each result sheet, was entered against each taxon in the column headed "Presumed cause of error". Where an error was modified by the findings of the internal AQC inspector, a code to indicate this was selected instead (either code 11 or 12).

SUMMARY OF AUDIT (For BMWP taxa only)

LOSSES: 1 GAINS: 2 OMISSIONS: 1

NET EFFECTS:

**ON BMWP SCORE 8
ON NO. OF SCORING TAXA 1**

- 1 No representative of family in vial
- 2 Alternative terrestrial specimen in vial
- 3 Posterior end only in vial
- 4 Empty shell or case or cast skin in vial

- 5 Specimen dead at time of sampling
- 6 Taxon in vial but not recorded
- 7 Mis-identification
- 8 Typographical error - wrong box ticked

- 9 Taxon missed in sorting
- 10 Unexplained error
- 11 Taxon added in internal AQC
- 12 Recorded taxon that was rejected by AQC analyst

Omission (*) = Recorded, not in vial but found by CEH in sample (no net loss or gain)

For those samples in which the vial of animals was damaged or missing, the "VIAL" sections of the report form were not applicable (N/a). Families not on the list but present in the sample were entered in the section under "SAMPLE" and "Additional taxa found in sample", as before. Families recorded on the list but not found by CEH were indicated in the section headed "Taxa not found in sample." If the vial of animals had been retained by the sorter, entries in this box could include the sole representative of a family which was removed, a family seen at the site which escaped or was released (without mention being made on the data sheet), inaccurate identification or the wrong family box being ticked on the data sheet.

The final section of the result sheet summarises the audit, giving details of the numbers of "losses", "gains" and "omissions" of families included in the BMWP scoring system only, together with the net effects on BMWP score and the number of scoring taxa.

5. RESULTS

The results of the Primary Audit for 2001 for the Agency are presented in Tables 1 to 58. For each Region, a summary of the basic audit results in terms of losses, gains and omissions (of BMWP taxa only) is followed by the statistics of these regional audit results centred on the target of acceptability of no more than two missed taxa per sample. These data are presented for each analyst, for their Area laboratory and for the Region and Agency as a whole. Then follows information on the net effects of the Primary Audit on the BMWP score and number of scoring taxa. Following this are listings for the Region of the taxa missed at family and species levels in the 2001 Primary Audit. Tables 59 and 60 summarise the statistics and net effects of the 2001 Primary Audit for the whole of the Agency. Tables 61 and 62 list all taxa, at family and species levels respectively, missed in sorting by the Agency's primary analysts. Data for the AQC Audit are presented in a separate report (Gunn *et al.*, 2001).

Estimating sample biases for the compare module of RIVPACS III+

The underestimation of the number of BMWP-scoring taxa is termed bias for the purpose of the compare module of RIVPACS III+. An estimate of bias is provided by the net gains (number of gains minus number of losses). The average net gains for each laboratory, Region and the Agency as a whole, are listed in Table 60 in the column "mean net effect on no. of taxa". These values may be used directly for RIVPACS. To estimate the bias over a different period to that covered by this audit, it is necessary to refer to the Primary Audit result sheets for individual samples. Note that estimates of bias should be based on the results of at least 20 audited samples. Further instructions are given in Clarke *et al.* (1997).

6. ACKNOWLEDGEMENTS

Grateful thanks to the Agency's project leader, John Murray-Bligh, who provided invaluable assistance in the development of the audit methodology and who has been a reliable source of helpful advice throughout the period of the audit
