## FOREWORD

The National Rivers Authority assumed responsibility for hydrometric data on vesting day 1 September 1989. The data presented in this Yearbook was managed by the Rivers and Regulation Division of Severn Trent Water Authority until vesting day and by the NRA's Severn-Trent Region thereafter.

Publication of the 1989 Yearbook has been timed to coincide with a sister volume on the 1989 drought. As with previous Yearbooks, it is impossible to summarise all data. On this occasion, the opportunity has been taken to place more emphasis on the measurement of low river flows. Accordingly, no apology is made for the inclusion of all the results of current meter gaugings during summer 1989. (This was the longest sustained period of low river flows since 1976.)

Elsewhere in the Yearbook, an indication is given in the Data Section of the type of data routinely prepared for established measurement stations. The full lists of stations are to be found in the second half of the volume under the Catalogue Section.

The Yearbook and Catalogue provide a summary of available processed hydro-metric data for 1989 together with selected details of low flow measurements. The sister volume specifically deals with the drought, its severity, its consequences and the lessons learned within the NRA Severn-Trent Region. Together, the two volumes provide a full picture of the way in which the drought was monitored and the water resources were managed in 1989.

The preparation of the Yearbook relies on teamwork between field hydro-metric staff based in the region's four Areas, regional data management staff and supporting services both in-house and contracted. Coordination of the Yearbook has been supervised by David Grimshaw, Senior Hydrologist with responsibility for Data Management based at the NRA's regional office at Solihull.

Inevitably in any enterprise of this scale, despite rigorous quality control of data, occasional mistakes do slip through. It would be appreciated if you could inform the Data Management Section of any errors so that they can be corrected. In this respect contact can be most readily made to:

NRA, Severn-Trent Region, Water Resources Section (Data Management)  
550 Streetsbrook Road, Solihull, B91 1QT, Tel 021-711-2324 Fax 021-722-5824.

Any suggestions for improvements to content or format of the Yearbook and/or Catalogue are welcomed.

The data summarised in this volume support all the technical functions of the NRA. As environmental awareness grows, so does the demand for accurate numeric information. Nowhere is this point more focussed than in the provision of hydrometric data. This Yearbook and Catalogue is presented in furtherance of the NRA's policy of openness and its aim to further heighten awareness of the variability of our water resources heritage.

R C Goodhew  
Principal, Water Resources

## A. HYDROMETRIC SUMMARY

### Introduction

The year was dominated by the very dry weather during the Summer which imposed an exceptionally heavy burden on many sections within the NRA, but none more so than the hydrometric and data processing staff.

The first low flow survey took place in late June, and by mid October a total of nearly fifty had been completed covering virtually the whole of the Region. Special attention was given to resource rivers and those where there were known problems at low flows.

Water Resources worked closely with the Licensing and Abstraction section to ensure that data was available to monitor flow recessions against threshold values. A larger than normal number of gaugings were required to support this function.

The Shropshire groundwater scheme came into operation for the first time and absorbed a considerable amount of the hydrometric manpower available in Upper Severn Area. When necessary staff were deployed outside their normal working area to ensure that hydrometric effort was concentrated where required. Headquarters staff were also used during surveys.

The year came to a close with flooding just before Christmas and a further surge in hydrometric activity, many major rivers being gauged at their highest levels for several years.

In all a total of 2440 gaugings were completed during 1989, of which almost 1700 were taken during the low flow period of late June to mid October, with 1360 alone during the period July to September when most surveys took place.

## B. CURRENT METER GAUGINGS FOR 1989.

A current meter gauging is a direct measurement of flow taken over a short period of time, usually between fifteen minutes and two hours depending on the size of river or stream. They are carried out for a variety of reasons the principal ones being to monitor the accuracy of rating curves used for flow processing, to check calibrations of ultrasonic and electromagnetic flowgauges, to monitor river flows for licensing and abstraction, to provide data for pollution control and quality monitoring and to investigate the hydrological characteristics of catchments.

### 1. FLOW GAUGINGS MAY-OCTOBER 1989.

The current meter gaugings in table 1 cover the period from 01/05/89 to 18/10/89. They demonstrate the gradual decline in flows over the region, although the data should be used with care as the number of gaugings available at any one site varies tremendously and the lowest flows which occurred need not necessarily be represented. A subset of this data is given in the various catchment and subcatchment specific low flow survey listings, but, given the exceptionally low flows of 1989, it was considered that a complete record of current meter gauging activity over the period should be included.

The data has been extracted from the database system into which gaugings processed by area staff are now captured directly. They are arranged by date within alphabetic site name within alphabetic river name.

The accuracy of current meter gauging data varies greatly according to site conditions. Percentage errors can be large at low flows. The results are expressed to two decimal places to provide sufficient precision for very small flows but current meter data cannot be said to be accurate to two decimal places of a megalitre. The data should be used with care and if in doubt consult the hydrometric staff within Water Resources.

The areas quoted in this and all other tables relate to the NRA operational areas in use from September 1 1989.

### 2. SPECIFIC SURVEY TABLES.

Once it became clear that lower than normal flows were going to be experienced surveys were organized to provide data on flow variations within specific subcatchments. The first one was on the River Derwent in late June. As the dry conditions persisted repeat and additional surveys were carried out so that all major catchments were covered at least once. Some smaller catchments of special interest were also included.

In all almost fifty separate surveys were completed, the last being on the 19 October. It was by far the most intensive series of flow measurement surveys since 1975/76.

Tables 2 to 9 show the results of groups of surveys covering either the same sites on different dates or sites within related subcatchments. The sites are all organized in downcatchment order. Most surveys were completed in one or two days and flows are comparable but the overall decline in

river flows was interrupted by rainfall, particularly on the 6/7 July, 9 and 14 August and 16 September. All flow data is given in megalitres per day.

Processed flow data has been included for virtually all flow measurement stations to provide information for additional sites and to demonstrate the relative change in flow rates between different surveys. These flows are marked (MDF) after the station name. For some sites both processed and current meter derived flows are given for some or all of the surveys. Differences are to be expected and may be due to a variety of causes, principally that the MDF is the mean for a 24 hour period starting 09.00 G.M.T. whilst a current meter gauging will typically measure the flow over a period of between fifteen minutes and two hours. However, some of the difference will be due to random and systematic errors in both gaugings and the flow calculation process. These may vary greatly from site to site.

The precise site chosen for gauging may vary from survey to survey. Where the quoted grid references vary significantly these are shown as separate sites as it cannot usually be established if there are any factors affecting flow between them.

The date given at the head of the table for each survey is that on which the majority of the gaugings were taken. Some surveys extended over two days, and this should be taken into consideration if the exact date is required. This can be confirmed by referring to the complete listing of gaugings in table 1.

When using the data the same comments regarding accuracy apply as for the previous listing of all low flow gaugings.

### C.PROCESSED FLOW DATA.

Producing acceptably accurate processed flow data is particularly difficult during exceptionally low flows. Some station records are still being reassessed and must be regarded as provisional.

#### 1. MONTHLY MEAN FLOWS FOR SELECTED SITES.

Table 10 shows long term monthly mean flows for thirty stations throughout the region out of the total of 90 processed to flows. The means for 1989 are also given together with a percentage comparison figure with the long term mean. Whilst the stations chosen are generally the more reliable ones at low flows, systematic errors are always greater at flow extremes and the data should be used with care. The data are presented in megalitres per day expressed to one decimal place although their accuracy is site dependent. The sites are in downcatchment order starting at the top of the R. Severn. Further information on site location is given in the level and flow station catalogue (table 13) and figure 17.

#### 2. ANNUAL HYDROGRAPHS AND FLOW DURATION CURVES.

Six stations have been selected for plotting as annual hydrographs to demonstrate flow variations throughout the year. These are shown in figures 2 to 7. Flow duration curves are also shown comparing 1989 with the whole of the flow record. Most of the catchments shown are affected to varying degrees by river regulation, abstraction and other artificial influences although the R.Dove to Izaak Walton is totally natural and the R.Rea at Hookagate only slightly less so. The site locations are shown in figure 1.

#### D. RAINFALL.

Rainfall is measured in two basic ways. The first is by the gauge being manually read at a set frequency, usually daily although it may be weekly or monthly. The second is where the gauge incorporates a recorder that logs more detailed information on the distribution of rainfall throughout the day. Severn Trent Region use tipping bucket gauges that generate a pulse for each half millimetre rainfall increment. An on site logger records the precise time of each pulse. These loggers are connected to the telephone network and can be interrogated remotely. Locations of both types of rainfall site are given in the catalogue section.

Most of the daily gauges in the region are operated by voluntary observers with data returns made monthly to Severn Trent Region headquarters. From there the data is passed on to the Meteorological Office for quality control and archiving. Subsequently the data is returned to headquarters for our own archives.

The rainfall event data is retrieved and archived on a micro computer based system that allows retrieval and graphical presentation of the data.

##### 1.DAILY RAINFALL TOTALS FOR SELECTED SITES.

Table 11 lists daily rainfall for 1989 at ten sites throughout the region out of the total of 300 for which daily data is available. The site locations are shown in Figure 1. Brackets indicate that the data has been apportioned by the M.O. from multi day totals. A comparison of the monthly totals against long term averages is given. The data is taken from microfiche provided by the M.O.

##### 2.AREAL RAINFALL FOR 1989.

Table 12 shows the monthly areal average data for the Region as a whole and sub areas within the Region.

Both sets of data illustrate the dry period between May and September with January and November also being considerably below average. The year was brought to a close by a wet December with most areas having almost twice the average.

Rainfall in millimetres (mm)

%LTA - monthly rainfall total as a percentage of the Long Term monthly Average (1941 to 1970).

## E.GROUNDWATER.

### 1.GROUNDWATER HYDROGRAPHS FOR 1989

The five examples of groundwater hydrographs shown in figures 8 to 12 show levels for 1989 compared with those for a number of previous years. Four of the five sites are on sandstone aquifers. Three of these four, Weeford Flats, Shrawley and Heathlanes, demonstrate clear annual cycles, levels usually rising in mid year in response to winter rainfall. This lag is much less evident for the Two Dale Barn site on Carboniferous limestone, which also demonstrates the sharp fluctuations in level typical of this aquifer. The site locations are shown in figure 1. These examples are selected from the 350 sites for which data is available.

All four sandstone aquifers show consistently falling levels throughout 1989 reflecting the low winter recharge and subsequent low summer rainfall, although all four are well above levels recorded during the 1976 drought.

## F. MISCELLANEOUS DATA

### 1. SOIL MOISTURE AND EVAPOTRANSPIRATION.

Figures 13 and 14 show the variations in soil moisture deficits and evapotranspiration throughout the year. All data is derived from the MORECS service run by the Meteorological Office.

The SMD values for the early part of the year show how slow the south eastern part of the region was in reaching field capacity. However, by early March the normal situation of zero SMD had been reached in all areas.

The shape of the April to December section of the curve is typical but maximum values were well above what would normally be expected, and were very consistent throughout the area. The heavy rainfall in late December quickly brought all areas back to field capacity.

The evapotranspiration data is shown as both actual and potential. Potential evapotranspiration is what would theoretically occur from a surface covered in short grass assuming moisture was always available in the soil. In persistent hot weather this need not necessarily be the case, leading to a difference between the two. In July the actual value was less than half the potential due to the high soil moisture deficits.

### 2. WATER TEMPERATURE

Eight river level sites have been equipped with water temperature sensors that feed data into the on site loggers. These are retrieved automatically along with the river level information.

Annual plots of mean daily water temperature data for two of these sites within the Severn catchment are shown in Figures 15 and 16 and their locations in figure 1. The basic patterns are as would be expected with temperature building up rapidly in May and June with the peak in July.

## SITE CATALOGUES

The following site catalogues show the current extent of the various networks. Requirements for hydrometric data are not static and the networks change over time to reflect this. Thus data is held for many sites that are now closed and do not appear in the following tables. Further information on these sites can be obtained on request from the data section.

The river level and flow station catalogue (table 13) has been split into two parts, part (a) listing major gauging stations and part (b) the minor sites. As a general rule minor sites are not processed and do not form part of the flood forecasting system. Figure 17 shows the locations of only the major sites.

The daily rainfall station catalogue (table 15) includes all sites within the region for which data is currently collected by the Meteorological Office. Whilst not all of these are operated by ourselves we do have access to the data from all sites listed.
