RIVER QUALITY REPORT

1993

1. River Quality

1.1 River Quality Objectives

During 1993, 571 sites were routinely monitored to assess 3814 km of rivers and canals having quality objectives. 35 reaches, representing 224 km or 5.9% of the total length failed to meet their objectives. Table 1 gives details of each failing reach.

The table below shows the number of reaches which have failed their quality objectives for each year since 1991.

	1991	1992	1993
Failing Reaches	85	62	35
Length (km)	500	309	224
	(13%)	(8%)	(6%)

This shows there has been a steady improvement from the position in 1991 when 500 km of watercourse or 13% of the total length failed to meet its objectives.

Table 3-illustrates graphically the length-of-rivers-meeting-their-quality-objectives since 1991.

1.2 Class Achievement

Table 2 gives details of the National Water Council (NWC) class achievement for all reaches during 1993. The table below shows the length of watercourse achieving good quality (class 1A and 1B) since 1991.

	1991	1992	1993
Class 1A (km)	1349	1065	1577
Class 1B (km)	1565	2070	1622
Total	2914 (76%)	3135 (82%)	3199 (84%)

This shows there has been an improvement in river quality over the past 3 years. In 1991, 76% of rivers achieved good quality, compared to 84% in 1993. Although the improvement has been steady, there was a reduction of the length of watercourse achieving class 1A during 1992.

2. General Quality Assessment

2.1 Introduction

The General Quality Assessment (GQA) scheme for assessing river quality, will be officially launched by the publication of the report 'The Quality of Rivers and Canals in England and Wales 1990 to 1992'. The scheme is non-statutory and will replace the existing National Water Council classification scheme. It will be applied consistently across the whole of the National Rivers Authority and will be used for the 5 yearly national river surveys. From April 1994 reporting of river quality to Head Office will be based on the new GQA classes.

2.2 Classification

The scheme will consist of four parts. Classifications will be based on chemistry, biology, aesthetics, and nutrient status. All these will be assessed separately but be reported together. Presently the only part of the scheme with firm proposals is the chemical classification. The standards are shown in the table below.

CLASS	CHEMICAL CLASSIFICATION		
	DO % sat 10 %ile	BOD mg/l 90 %ile	Ammonia mg/l N 90 %ile
A	80	2.5	0.25
B	70	4.0	0.6
C	60	6.0	1.3
D	50	8.0	2.5
E	20	15.0	9.0
F	<20		

Two things are worth noting:

- a) There are six classes, A - F, which replace the old familiar 1A - 4.
- b) The quality standards are expressed as calculated 90 and 10 percentiles, rather than 95 and 5 percentiles qualified by the look-up table.

It must be stressed at this stage that the two systems are not strictly comparable.

The new scheme will be only be used to assign the most likely class to a stretch of river. It will not be used to assess compliance against quality objectives. Until

statutory water quality objectives are formally introduced, the existing river quality objectives will continue to be used for consent setting. The new GQA scheme will be reported alongside the old scheme over the next year.

2.3 Class Achievement

Table 2 gives details of the GQA class achieved by all reaches during 1993.

Table 4 shows the overall class achievement for rivers having quality objectives since 1991. As with the old NWC scheme, a steady improvement in river quality can be seen. In 1993, 2038 km of watercourse achieved class A and B compared to 1440 km in 1991. It should be noted that for the national river surveys, achievement will be assessed on 3 years of data.

Table 5 shows the class achievement in each area during 1993.

3. EC Freshwater Fish Directive

- 3.1 A total length of 1470 km of freshwater river is designated under the EC Freshwater Fish Directive 78/559/EEC. Of this, 504 km is designated as salmonid, and 966 km is designated as cyprinid. 173 sampling sites are used to assess compliance against the water quality standards set in the directive.
- 3.2 Table 6 gives details of the 11 sites which failed to meet these standards in 1993. This is two more than reported for 1992; 5 sites have left the table while 7 sites have entered the table. The overall length of failing watercourse in 1993 was 11.4 km for salmonid waters and 50.5 km for cyprinid waters. The figures for 1992 are 41.7 km and 14.4 km respectively. There has been a reduction in the length of failing salmonid waters which in 1992 was largely due to lower dissolved oxygen levels. However, there has been an increase in the length of failing cyprinid waters mainly due to ammoniacal nitrogen.
- 3.3 Of the failing salmonid waters, the two sites on the R.Loddon failed the dissolved oxygen standard in both 1992 and 1993. Of the failing cyprinid waters, the site on the Bourne (North) and the R.Hart failed the standard for ammoniacal nitrogen in 1991, 1992, and 1993. The two sites on the R.Ray (Wilts) below Swindon STW have returned to the failing list because of ammoniacal nitrogen.

4. EC Dangerous Substances Directive

- 4.1 Table 7 gives details of the six freshwater sites which failed to achieve the standards set in the EC Dangerous Substances Directive during 1993. This is one more site than reported in 1992. One site has left the table while two sites on the R.Lee have entered the table.

4.2 The failures against the standard for total HCH on the Wandle, Hogsmill, and Lee were marginal. The sampling points are all below significant discharges of sewage effluent. The failure against the zinc standard on the Collins Brook is attributed to a specific trade discharge, while the failure against the dissolved iron standard on the Pyestock Tributary has been attributed to natural causes.

5. The Tideway

5.1 Tables 8 to 11 detail the compliance of the three tideway reaches against their objectives for each quarter in 1993. There were no failures against the dissolved oxygen standards, but there were failures against the standard set for the BMWP score at Battersea, Hammersmith, and Kew.

5.2 During the first quarter water quality was very good. Dissolved oxygen levels were in excess of 80% saturation in the upper reaches and 45% in the middle reaches. In early spring relatively low freshwater flows and prolonged sunshine promoted algal growths causing supersaturation in the upper reaches. Dissolved oxygen levels varied between 90% and 120% saturation.

5.3 During the second and third quarters water quality was generally satisfactory. Dissolved oxygen levels were generally above 50% saturation in the upper reaches and between 30% and 50% in the middle reaches. Periods of heavy rainfall caused significant discharges of storm sewage into the tideway, but relatively high freshwater flows ensured that any deterioration in water quality was short-lived. "Thames Bubbler" was deployed only once during the year - on August 11th as a pre-emptive measure - but dissolved oxygen levels never fell below 50% saturation. However, heavy rainfall on 7/8 September caused dissolved oxygen levels to fall to 27% saturation in the upper reaches. In the middle reaches dissolved oxygen levels fell to 30% saturation for a short period in June due to operational problems at Crossness STW.

5.4 During the last quarter of 1993 dissolved oxygen levels in the upper reaches were between 70% and 80% saturation despite significant discharges of storm sewage. In the middle reaches, dissolved oxygen levels fell to 15% saturation at the beginning of October due to significant inputs of storm sewage, but soon recovered to 30% saturation and from November remained around 50% saturation.

5.5 Table 12 gives details of only two sites in the tideway which failed the standards set in the EC Dangerous Substances Directive. These were marginal failures against the standard set for total HCH.
